the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 669: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, debug information are logged.		false	false	false
es.session.index.field	Name of the field in the record defining the ES index containing the web session documents.		null	false	false
es.session.type.name	Name of the ES type of web session documents.		null	false	false
es.event.index.prefix	Prefix of the index containing the web event documents.		null	false	false
es.event.type.name	Name of the ES type of web event documents.		null	false	false
es.mapping.event.to.session.index.name	Name of the ES index containing the mapping of web session documents.		null	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false
session.timeout	session timeout in sec		1800	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
newSessionReason.out.field	the name of the field containing the reason why a new session was created => will override default value if set		reasonForNewSession	false	false
transactionIds.out.field	the name of the field containing all transactionIds => will override default value if set		transactionIds	false	false
source_of_traffic.suffix	Prefix for the source of the traffic related fields		source_of_traffic	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 670: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 671: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 672: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Table 677: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 678: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 679: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 682: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 683: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 684: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 685: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 690: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 695: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 696: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 697: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 698: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 699: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 700: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 702: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 703: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 704: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 707: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 708: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 709: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 710: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 715: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 721: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 722: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 724: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 725: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 727: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 728: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 729: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

Extra informations

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 732: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 733: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 734: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 735: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 740: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 741: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 742: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 746: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 747: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 748: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 752: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
es.index.field	the name of the incoming records field containing es index name to use in multiget query.		null	false	false
es.type.field	the name of the incoming records field containing es type name to use in multiget query		null	false	false
es.ids.field	the name of the incoming records field containing es document Ids to use in multiget query		null	false	false
es.includes.field	the name of the incoming records field containing es includes to use in multiget query		null	false	false
es.excludes.field	the name of the incoming records field containing es excludes to use in multiget query		null	false	false

Extra informations

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 753: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 754: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 755: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

(default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

Class

com.hurence.logisland.processor.DetectOutliers

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 758: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 759: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 760: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 761: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 763: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

Table 764: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 766: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 771: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 772: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToGeo

Tags

geo, enrich, ip

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 773: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 775: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 776: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 778: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 779: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 780: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

(default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 783: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 784: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 785: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 786: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 791: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false
session.timeout	session timeout in sec		1800	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
newSessionReason.out.field	the name of the field containing the reason why a new session was created => will override default value if set		reasonForNewSession	false	false
transactionIds.out.field	the name of the field containing all transactionIds => will override default value if set		transactionIds	false	false
source_of_traffic.suffix	Prefix for the source of the traffic related fields		source_of_traffic	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 796: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 797: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 798: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 801: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 803: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 804: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 805: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 808: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 809: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 810: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 811: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 815: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 816: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 821: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 822: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 823: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 826: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 828: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 829: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 830: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 833: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 834: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 835: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 836: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 841: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 844: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 846: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 847: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 848: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 850: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 851: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 853: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 854: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 855: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 858: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 859: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 860: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 861: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 866: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 867: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 868: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

Class

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

User-Agent, clickstream, DMP

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 869: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 871: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 872: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 873: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 878: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 879: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 880: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Class

com.hurence.logisland.processor.webAnalytics.ConsolidateSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 881: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 883: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 884: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 885: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 886: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.bro.ParseBroEvent

Tags

bro, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 889: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

“id.resp_h”: “172.17.0.3”,

"ts": 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 891: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 896: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 897: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 899: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 900: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 901: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 903: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 904: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 905: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 908: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 909: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 910: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 911: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

“record_time”: 1487597792782

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 916: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webAnalytics.SetSourceOfTraffic

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 921: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 922: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 923: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 925: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 928: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 929: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 930: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 931: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 933: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 934: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 935: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 936: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_resp": true

"uid": "Ct3Ms01I3Yc6pmMZx7"

"conn_state": "OTH"

"id_orig_h": "172.17.0.2"

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 940: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 941: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 944: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 946: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 947: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 948: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 951: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 953: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 954: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 955: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 958: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 959: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 960: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 961: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 966: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 969: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 971: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 972: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 973: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 975: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 976: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 978: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 979: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 980: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 983: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 984: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 985: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 986: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 990: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 991: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

record, fields, Decode

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 992: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 993: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

Class

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

User-Agent, clickstream, DMP

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 994: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 996: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 997: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 998: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Table 1001: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1003: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1004: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1005: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Class

com.hurence.logisland.processor.webAnalytics.ConsolidateSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1006: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

Extra informations

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1008: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1009: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1010: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1011: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchQuery

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1012: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1013: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.bro.ParseBroEvent

Tags

bro, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1014: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

“id.resp_h”: “172.17.0.3”,

"ts": 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1016: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 1019: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 1021: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1022: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

com.hurence.logisland.processor.enrichment.IpToGeo

Tags

geo, enrich, ip

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1023: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1024: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1025: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1026: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1028: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1029: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1030: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)

- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1033: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1034: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1035: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1036: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1041: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
newSessionReason.out.field	the name of the field containing the reason why a new session was created => will override default value if set		reasonForNewSession	false	false
transactionIds.out.field	the name of the field containing all transactionIds => will override default value if set		transactionIds	false	false
source_of_traffic.prefix	Prefix for the source of the traffic related fields		source_of_traffic	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1046: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1047: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1048: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1051: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1053: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1054: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1055: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1058: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1059: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1060: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1061: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1065: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1066: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 1069: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 1071: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1072: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1073: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1076: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1078: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1079: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1080: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1083: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1084: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1085: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1086: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1091: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 1094: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webanalytics.SetSourceOfTraffic

Tags

session, traffic, source, web, analytics

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1096: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1097: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Module

Tags

geo, enrich, ip

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1098: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1100: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1101: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1103: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1104: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1105: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1106: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

Extra informations

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1108: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1109: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1110: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1111: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1115: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1116: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Extra informations

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

URIDecoder

Decode one or more field containing an URI with possibly special chars encoded ...

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1117: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

number.of.future.sessions	The number of sessions to look for when searching session of last events		1	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1122: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The name of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1123: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1124: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1125: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1126: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1127: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1129: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1130: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1131: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1134: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Table 1135: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1136: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1137: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1142: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 1143: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Name	Description	Allowable Values	Default Value	Sensitive	EL
record.es.index.output.field.name	The field where index name to store record will be stored		es_index	false	false
record.es.type.output.field.name	The field where type name to store record will be stored		es_type	false	false
number.of.future.session.to.look	The number of session to look for when searching session of last events		1	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1148: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1149: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1150: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1155: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1156: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1157: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1158: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1160: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1161: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1162: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1163: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```

bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1167: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1168: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

record, fields, Decode

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1169: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 1174: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1175: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

geo, enrich, ip

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1176: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 1178: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Table 1179: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1181: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1182: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1183: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)

- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1186: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1187: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1188: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1189: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1193: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1194: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1195: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1200: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1201: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1202: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 1205: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Table 1206: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
es.index.field	the name of the incoming records field containing es index name to use in multiget query.		null	false	false
es.type.field	the name of the incoming records field containing es type name to use in multiget query		null	false	false
es.ids.field	the name of the incoming records field containing es document Ids to use in multiget query		null	false	false
es.includes.field	the name of the incoming records field containing es includes to use in multiget query		null	false	false
es.excludes.field	the name of the incoming records field containing es excludes to use in multiget query		null	false	false

Extra informations

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1207: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1208: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1209: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1212: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1213: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1214: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1215: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1216: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1217: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1218: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1220: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1221: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1227: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1228: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1230: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1231: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1233: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1234: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1235: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

Extra informations

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1238: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1239: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1240: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1241: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"history": "Cc"

"tunnel_parents": []

"id_orig_p": 56762

"local_resp": true

"uid": "Ct3Ms01I3Yc6pmMZx7"

"conn_state": "OTH"

"id_orig_h": "172.17.0.2"

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

Module

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1245: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1246: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

record, fields, Decode

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1247: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1248: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
url.fields	List of fields (URL) to decode and optionnaly the output field for the url modified. Syntax should be <name>,<name:newName>,...,<name>. So fields name can not contain ',' nor ':'		null	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false
url.keep.params	List of param names to keep in the input url (others will be removed). Can not be given at the same time as url.remove.params or url.remove.all		null	false	false
url.remove.params	List of param names to remove from the input url (others will be kept). Can not be given at the same time as url.keep.params or url.remove.all		null	false	false
url.remove.all	Remove all params if true.		null	false	false
parameter.separator	the character to use to separate the parameters in the query part of the uris		&	false	false
key.value.separator	the character to use to separate the parameter name from the parameter value in the query part of the uris		=	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLDecoder

Decode one or more field containing an URL with possibly special chars encoded ...

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1249: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

Table 1250: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Name	Description	Allowable Values	Default Value	Sensitive	EL
record.es.index.output.field.name	The field name where index name to store record will be stored		es_index	false	false
record.es.type.output.field.name	The field name where type name to store record will be stored		es_type	false	false
number.of.future.session.to.look	The number of session to look for when searching session of last events		1	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1252: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1253: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1254: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 1256: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1257: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1259: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1260: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1261: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1264: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1265: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1266: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1267: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1272: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1273: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

CalculWebSession

This processor creates web-sessions based on incoming web-events. Firstly, web-events are grouped by their session identifier and processed in chronological order. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

record.es.type.field.name	The field name where type name to store record will be stored		es_type	false	false
number.of.future.session.to.wait	The number of session to wait for when searching session of last events		1	false	false

Extra informations

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1279: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1280: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1281: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1286: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1287: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1288: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1291: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1292: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1293: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1294: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Table 1295: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1296: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

Table 1298: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1299: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 1300: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
decode.fields	List of fields (URL) to decode		null	false	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

URLCleaner

Remove some or all query parameters from one or more field containing an uri which should be preferably encoded. If the uri is not encoded the behaviour is not defined in case the decoded uri contains '#', '?', '=', '&' which were encoded. Indeed this processor assumes that the start of query part of the uri start at the first '?' then end at the first '#' or at the end of the uri as specified by rfc3986 available at https://tools.ietf.org/html/rfc3986#section-3.4. We assume as well that key value pairs are separed by '=', and are separed by '&': exemple 'param1=value1&param2=value2'. The processor can remove also parameters that have only a name and no value. The character used to separate the key and the value '=' is configurable. The character used to separate two parameters '&' is also configurable.

CalculWebSession

This processor creates web-sessions based on incoming web-events. Firstly, web-events are grouped by their session identifier and processed in chronological order. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Supported by current system is : [Asia/Aden, America/Cuiaba, Etc/GMT+9, Etc/GMT+8, Africa/Nairobi, America/Marigot, Asia/Aqtau, Pacific/Kwajalein, America/El_Salvador, Asia/Pontianak, Africa/Cairo, Pacific/Pago_Pago, Africa/Mbabane, Asia/Kuching, Pacific/Honolulu, Pacific/Rarotonga, America/Guatemala, Australia/Hobart, Europe/London, America/Belize, America/Panama, Asia/Chungking, America/Managua, America/Indiana/Petersburg, Asia/Yerevan, Europe/Brussels, GMT, Europe/Warsaw, America/Chicago, Asia/Kashgar, Chile/Continental, Pacific/Yap, CET, Etc/GMT-1, Etc/GMT-0, Europe/Jersey, America/Tegucigalpa, Etc/GMT-5, Europe/Istanbul, America/Eirunepe, Etc/GMT-4, America/Miquelon, Etc/GMT-3, Europe/Luxembourg, Etc/GMT-2, Etc/GMT-9, America/Argentina/Catamarca, Etc/GMT-8, Etc/GMT-7, Etc/GMT-6, Europe/Zaporozhye, Canada/Yukon, Canada/Atlantic, Atlantic/St_Helena, Australia/Tasmania, Libya, Europe/Guernsey, America/Grand_Turk, US/Pacific-New, Asia/Samarkand, America/Argentina/Cordoba, Asia/Phnom_Penh, Africa/Kigali, Asia/Almaty, US/Alaska, Asia/Dubai, Europe/Isle_of_Man, America/Araguaina, Cuba, Asia/Novosibirsk, America/Argentina/Salta, Etc/GMT+3, Africa/Tunis, Etc/GMT+2, Etc/GMT+1, Pacific/Fakaofo, Africa/Tripoli, Etc/GMT+0, Israel, Africa/Banjul, Etc/GMT+7, Indian/Comoro, Etc/GMT+6, Etc/GMT+5, Etc/GMT+4, Pacific/Port_Moresby, US/Arizona, Antarctica/Syowa, Indian/Reunion, Pacific/Palau, Europe/Kaliningrad, America/Montevideo, Africa/Windhoek, Asia/Karachi, Africa/Mogadishu, Australia/Perth, Brazil/East, Etc/GMT, Asia/Chita, Pacific/Easter, Antarctica/Davis, Antarctica/McMurdo, Asia/Macao, America/Manaus, Africa/Freetown, Europe/Bucharest, Asia/Tomsk, America/Argentina/Mendoza, Asia/Macau, Europe/Malta, Mexico/BajaSur, Pacific/Tahiti, Africa/Asmera, Europe/Busingen, America/Argentina/Rio_Gallegos,		null	false	false

Table 1305 – continued from previous page

Name	Description	Allowable Values	Default Value	Sensitive	EL
record.es.index.output.field.name	The field name where index name to store record will be stored		es_index	false	false
record.es.type.output.field.name	The field name where type name to store record will be stored		es_type	false	false
number.of.future.session.to.look	The number of session to look for when searching session of last events		1	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.prefix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1306: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The name of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Timeout validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution

occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1307: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1308: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1313: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1314: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 1315: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webanalytics.ConsolidateSession

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1316: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 1318: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1319: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false
