Engine-spark

Find below the list.

ConsoleStructuredStreamProviderService

Provide a ways to print output in console in a StructuredStream streams

Class

com.hurence.logisland.stream.spark.structured.provider.ConsoleStructuredStreamProviderService

Tags

None.

Properties

This component has no required or optional properties.

Extra informations

No additional information is provided

DummyRecordStream

No description provided.

Class

com.hurence.logisland.stream.spark.DummyRecordStream

Tags

None.

Properties

This component has no required or optional properties.

Extra informations

No additional information is provided

KafkaConnectBaseProviderService

No description provided.

Class

com.hurence.logisland.stream.spark.provider.KafkaConnectBaseProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 1: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kc.connector.class	The class canonical name of the kafka connector to use.		null	false	false
kc.connector.properties	The properties (key=value) for the connector.			false	false
kc.data.key.converter	Key converter class		null	false	false
kc.data.key.converter.properties	Key converter properties			false	false
kc.data.value.converter	Value converter class		null	false	false
kc.data.value.converter.properties	Value converter properties			false	false
kc.worker.tasks.max	Max number of threads for this connector		1	false	false
kc.partitions.max	Max number of partitions for this connector.		null	false	false
kc.connector.offset.backing.store	The backing store to be used.	memory (Standalone in memory offset backing store. Not suitable for clustered deployments unless source is unique or stateless), file (Standalone filesystem based offset backing store. You have to specify the property offset.storage.file.filename for the file path.Not suitable for clustered deployments unless source is unique or standalone), kafka (Distributed kafka topic based offset backing store. See the javadoc of class org.apache.kafka.connect.storage.KafkaOffsetBackingStore for the configuration options.This backing store is well suited for distributed deployments.)	memory	false	false
kc.connector.offset.backing.store.properties	Properties to configure the offset backing store			false	false

Extra informations

No additional information is provided

KafkaConnectStructuredSinkProviderService

No description provided.

Class

com.hurence.logisland.stream.spark.provider.KafkaConnectStructuredSinkProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 2: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kc.connector.class	The class canonical name of the kafka connector to use.		null	false	false
kc.connector.properties	The properties (key=value) for the connector.			false	false
kc.data.key.converter	Key converter class		null	false	false
kc.data.key.converter.properties	Key converter properties			false	false
kc.data.value.converter	Value converter class		null	false	false
kc.data.value.converter.properties	Value converter properties			false	false
kc.worker.tasks.max	Max number of threads for this connector		1	false	false
kc.partitions.max	Max number of partitions for this connector.		null	false	false
kc.connector.offset.backing.store	The backing store backing store to be used.	memory (Standalone in memory offset backing store. Not suitable for clustered deployments unless source is unique or stateless), file (Standalone filesystem based offset backing store. You have to specify the property offset.storage.file.filename for the file path.Not suitable for clustered deployments unless source is unique or standalone), kafka (Distributed kafka topic based offset backing store. See the javadoc of class org.apache.kafka.connect.storage.KafkaOffsetBackingStore for the configuration options.This backing store is well suited for distributed deployments.)	memory	false	false
kc.connector.offset.backing.store.properties	Properties to configure the offset backing store			false	false

Extra informations

No additional information is provided

KafkaConnectStructuredSourceProviderService

No description provided.

Class

com.hurence.logisland.stream.spark.provider.KafkaConnectStructuredSourceProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 3: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kc.connector.class	The class canonical name of the kafka connector to use.		null	false	false
kc.connector.properties	The properties (key=value) for the connector.			false	false
kc.data.key.converter	Key converter class		null	false	false
kc.data.key.converter.properties	Key converter properties			false	false
kc.data.value.converter	Value converter class		null	false	false
kc.data.value.converter.properties	Value converter properties			false	false
kc.worker.tasks.max	Max number of threads for this connector		1	false	false
kc.partitions.max	Max number of partitions for this connector.		null	false	false
kc.connector.offset.backing.store	The backing store backing store to be used.	memory (Standalone in memory offset backing store. Not suitable for clustered deployments unless source is unique or stateless), file (Standalone filesystem based offset backing store. You have to specify the property offset.storage.file.filename for the file path.Not suitable for clustered deployments unless source is unique or standalone), kafka (Distributed kafka topic based offset backing store. See the javadoc of class org.apache.kafka.connect.storage.KafkaOffsetBackingStore for the configuration options.This backing store is well suited for distributed deployments.)	memory	false	false
kc.connector.offset.backing.store.properties	Properties to configure the offset backing store			false	false

Extra informations

No additional information is provided

KafkaRecordStreamDebugger

No description provided.

Class

com.hurence.logisland.stream.spark.KafkaRecordStreamDebugger

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 4: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kafka.error.topics	Sets the error topics Kafka topic name		_errors	false	false
kafka.input.topics	Sets the input Kafka topic name		_raw	false	false
kafka.output.topics	Sets the output Kafka topic name		_records	false	false
avro.input.schema	the avro schema definition		null	false	false
avro.output.schema	the avro schema definition for the output serialization		null	false	false
kafka.input.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.output.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.error.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as	com.hurence.logisland.serializer.JsonSerializer	false	false

Extra informations

No additional information is provided

KafkaRecordStreamHDFSBurner

No description provided.

Class

com.hurence.logisland.stream.spark.KafkaRecordStreamHDFSBurner

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 5: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kafka.error.topics	Sets the error topics Kafka topic name		_errors	false	false
kafka.input.topics	Sets the input Kafka topic name		_raw	false	false
kafka.output.topics	Sets the output Kafka topic name		_records	false	false
avro.input.schema	the avro schema definition		null	false	false
avro.output.schema	the avro schema definition for the output serialization		null	false	false
kafka.input.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.output.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.error.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as	com.hurence.logisland.serializer.JsonSerializer	false	false

Extra informations

No additional information is provided

KafkaRecordStreamParallelProcessing

No description provided.

Class

com.hurence.logisland.stream.spark.KafkaRecordStreamParallelProcessing

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 6: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kafka.error.topics	Sets the error topics Kafka topic name		_errors	false	false
kafka.input.topics	Sets the input Kafka topic name		_raw	false	false
kafka.output.topics	Sets the output Kafka topic name		_records	false	false
avro.input.schema	the avro schema definition		null	false	false
avro.output.schema	the avro schema definition for the output serialization		null	false	false
kafka.input.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.output.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.error.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as	com.hurence.logisland.serializer.JsonSerializer	false	false

Extra informations

No additional information is provided

KafkaRecordStreamSQLAggregator

This is a stream capable of SQL query interpretations.

Class

com.hurence.logisland.stream.spark.KafkaRecordStreamSQLAggregator

Tags

stream, SQL, query, record

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 7: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kafka.error.topics	Sets the error topics Kafka topic name		_errors	false	false
kafka.input.topics	Sets the input Kafka topic name		_raw	false	false
kafka.output.topics	Sets the output Kafka topic name		_records	false	false
avro.input.schema	the avro schema definition		null	false	false
avro.output.schema	the avro schema definition for the output serialization		null	false	false
kafka.input.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.output.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.error.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as	com.hurence.logisland.serializer.JsonSerializer	false	false

Extra informations

No additional information is provided

KafkaStreamProcessingEngine

No description provided.

Class

com.hurence.logisland.engine.spark.KafkaStreamProcessingEngine

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 8: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
spark.app.name	The application name		logisland	false	false
spark.master	The url to Spark Master		local[2]	false	false
spark.monitoring.driver.port	The port for exposing monitoring metrics		null	false	false
spark.yarn.deploy-mode	The yarn deploy mode		null	false	false
spark.yarn.queue	The name of the YARN queue		default	false	false
spark.driver.memory	The memory size for Spark driver		512m	false	false
spark.executor.memory	The memory size for Spark executors		1g	false	false
spark.driver.cores	The number of cores for Spark driver		4	false	false
spark.executor.cores	The number of cores for Spark driver		1	false	false
spark.executor.instances	The number of instances for Spark app		null	false	false
spark.serializer	Class to use for serializing objects that will be sent over the network or need to be cached in serialized form		org.apache.spark.serializer.KryoSerializer	false	false
spark.streaming.blockInterval	Interval at which data received by Spark Streaming receivers is chunked into blocks of data before storing them in Spark. Minimum recommended - 50 ms		350	false	false
spark.streaming.kafka.maxRatePerPartition	Maximum rate (number of records per second) at which data will be read from each Kafka partition		5000	false	false
spark.streaming.batchDuration	Number of seconds per batch		2000	false	false

Continued on next page

Table 8 – continued from previous page

Name	Description	Allowable Values	Default Value	Sensitive	EL
spark.streaming.backpressure.enabled	This enables the Spark Streaming to control the receiving rate based on the current batch scheduling delays and processing times so that the system receives only as fast as the system can process.		false	false	false
spark.streaming.unpersist	Force RDDs generated and persisted by Spark Streaming to be automatically unpersisted from Spark's memory. The raw input data received by Spark Streaming is also automatically cleared. Setting this to false will allow the raw data and persisted RDDs to be accessible outside the streaming application as they will not be cleared automatically. But it comes at the cost of higher memory usage in Spark.		false	false	false
spark.ui.port	No Description Provided.		4050	false	false
spark.streaming.kafka.maxRetries	No Description Provided.		-1	false	false
spark.streaming.kafka.maxRatePerPartition	Maximum rate (number of records per second) at which data will be read from each Kafka partition		3	false	false
spark.streaming.ui.retainedBatches	How many batches the Spark Streaming UI and status APIs remember before garbage collecting.		200	false	false
spark.streaming.receiver.writeAheadLog.enable	Enable write ahead logs for receivers. All the input data received through receivers will be saved to write ahead logs that will allow it to be recovered after driver failures.		false	false	false
spark.yarn.maxAppAttempts	Because Spark driver and Application Master share a single JVM, any error in Spark driver stops our long-running job. Fortunately it is possible to configure maximum number of attempts that will be made to re-run the application. It is reasonable to set higher value than default 2 (derived from YARN cluster property yarn.resourcemanager.am.max-attempts). 4 works quite well, higher value may cause unnecessary restarts even if the reason of the failure is permanent.		4	false	false
spark.yarn.am.attemptFailuresValidityInterval	If the application runs for days or weeks without restart or redeployment on highly utilized cluster, 4 attempts could be exhausted in few hours. To avoid this situation, the attempt counter should be reset on every hour of so.		1h	false	false

Continued on next page

Table 8 – continued from previous page

Name	Description	Allowable Values	Default Value	Sensitive	EL
spark.yarn.max.executor.failures	maximum number of executor failures before the application fails. By default it is max(2 * num executors, 3), well suited for batch jobs but not for long-running jobs. The property comes with corresponding validity interval which also should be set.8 * num_executors		20	false	false
spark.yarn.executor.failuresValidityInterval	If the application runs for days or weeks without restart or redeployment on highly utilized cluster, x attempts could be exhausted in few hours. To avoid this situation, the attempt counter should be reset on every hour of so.		1h	false	false
spark.task.maxFailures	For long-running jobs you could also consider to boost maximum number of task failures before giving up the job. By default tasks will be retried 4 times and then job fails.		8	false	false
spark.memory.fraction	expresses the size of M as a fraction of the (JVM heap space - 300MB) (default 0.75). The rest of the space (25%) is reserved for user data structures, internal metadata in Spark, and safeguarding against OOM errors in the case of sparse and unusually large records.		0.6	false	false
spark.memory.storageFraction	expresses the size of R as a fraction of M (default 0.5). R is the storage space within M where cached blocks immune to being evicted by execution.		0.5	false	false
spark.scheduler.mode	The scheduling mode between jobs submitted to the same SparkContext. Can be set to FAIR to use fair sharing instead of queueing jobs one after another. Useful for multi-user services.	FAIR (fair sharing), FIFO (queueing jobs one after another)	FAIR	false	false
spark.properties.file	Load using –properties-file option while submitting spark job		null	false	false
java.library.path	The java library path to use with mesos.		null	false	false
spark.cores.max	The maximum number of total executor core with mesos.		null	false	false

Extra informations

No additional information is provided

KafkaStructuredStreamProviderService

Provide a ways to use kafka as input or output in StructuredStream streams

Class

com.hurence.logisland.stream.spark.structured.provider.KafkaStructuredStreamProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 9: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
kafka.error.topics	Sets the error topics Kafka topic name		_errors	false	false
kafka.input.topics	Sets the input Kafka topic name		_raw	false	false
kafka.output.topics	Sets the output Kafka topic name		_records	false	false
avro.input.schema	the avro schema definition		null	false	false
avro.output.schema	the avro schema definition for the output serialization		null	false	false
kafka.input.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.output.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as json blocs supporting nested objects/arrays), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), com.hurence.logisland.serializer.BytesArraySerializer (serialize events as byte arrays), com.hurence.logisland.serializer.StringSerializer (serialize events as string), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
kafka.error.topics.serializer	No Description Provided.	com.hurence.logisland.serializer.KryoSerializer (serialize events as binary blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.ExtendedJsonSerializer (serialize events as	com.hurence.logisland.serializer.JsonSerializer	false	false

Extra informations

No additional information is provided

LocalFileStructuredStreamProviderService

Provide a way to read a local file as input in StructuredStream streams

Class

com.hurence.logisland.stream.spark.structured.provider.LocalFileStructuredStreamProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 10: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
local.input.path	the location of the directory of files to be loaded. All files inside the directory will be taked as input		null	false	false
max.files.per.trigger	maximum number of new files to be considered in every trigger (default: no max)		null	false	false
latest.first	whether to processs the latest new files first, useful when there is a large backlog of files (default: false)		null	false	false
filename.only	whether to check new files based on only the filename instead of on the full path (default: false). With this set to *true*, the following files would be considered as the same file, because their filenames, "dataset.txt", are the same: "file:///dataset.txt" "s3://a/dataset.txt" "s3n://a/b/dataset.txt" "s3a://a/b/c/dataset.txt"		null	false	false

Extra informations

No additional information is provided

MQTTStructuredStreamProviderService

Provide a ways to use Mqtt a input or output in StructuredStream streams

Class

com.hurence.logisland.stream.spark.structured.provider.MQTTStructuredStreamProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 11: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
mqtt.broker.url	brokerUrl A url MqttClient connects to. Set this or path as the url of the Mqtt Server. e.g. tcp://localhost:1883		tcp://localhost:1883	false	false
mqtt.clean.session	cleanSession Setting it true starts a clean session, removes all checkpointed messages by a previous run of this source. This is set to false by default.		true	false	false
mqtt.client.id	clientID this client is associated. Provide the same value to recover a stopped client.		null	false	false
mqtt.connection.timeout	connectionTimeout Sets the connection timeout, a value of 0 is interpreted as wait until client connects. See MqttConnectOptions.setConnectionTimeout for more information		5000	false	false
mqtt.keep.alive	keepAlive Same as MqttConnectOptions.setKeepAliveInterval.		5000	false	false
mqtt.password	password Sets the password to use for the connection		null	false	false
mqtt.persistence	persistence By default it is used for storing incoming messages on disk. If memory is provided as value for this option, then recovery on restart is not supported.		memory	false	false
mqtt.version	mqttVersion Same as MqttConnectOptions.setMqttVersion		5000	false	false
mqtt.username	username Sets the user name to use for the connection to Mqtt Server. Do not set it, if server does not need this. Setting it empty will lead to errors.		null	false	false
mqtt.qos	QoS The maximum quality of service to subscribe each topic at.Messages published at a lower quality of service will be received at the published QoS.Messages published at a higher quality of service will be received using the QoS specified on the subscribe		0	false	false
mqtt.topic	Topic MqttClient subscribes to.		null	false	false

Extra informations

No additional information is provided

RateStructuredStreamProviderService

Generates data at the specified number of rows per second, each output row contains a timestamp and value. Where timestamp is a Timestamp type containing the time of message dispatch, and value is of Long type containing the message count, starting from 0 as the first row. This source is intended for testing and benchmarking. Used in StructuredStream streams.

Class

com.hurence.logisland.stream.spark.structured.provider.RateStructuredStreamProviderService

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 12: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
local.file.input.path	the location of the file to be loaded		null	false	false
local.file.output.path	the location of the file to be writen		null	false	false
has.csv.header	Is this a csv file with the first line as a header		true	false	false
csv.delimiter	the delimiter		,	false	false

Extra informations

No additional information is provided

RemoteApiStreamProcessingEngine

No description provided.

Class

com.hurence.logisland.engine.spark.RemoteApiStreamProcessingEngine

Tags

None.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 13: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
spark.app.name	The application name		logisland	false	false
spark.master	The url to Spark Master		local[2]	false	false
spark.monitoring.driver.port	The port for exposing monitoring metrics		null	false	false
spark.yarn.deploy-mode	The yarn deploy mode		null	false	false
spark.yarn.queue	The name of the YARN queue		default	false	false
spark.driver.memory	The memory size for Spark driver		512m	false	false
spark.executor.memory	The memory size for Spark executors		1g	false	false
spark.driver.cores	The number of cores for Spark driver		4	false	false
spark.executor.cores	The number of cores for Spark driver		1	false	false
spark.executor.instances	The number of instances for Spark app		null	false	false
spark.serializer	Class to use for serializing objects that will be sent over the network or need to be cached in serialized form		org.apache.spark.serializer.KryoSerializer	false	false
spark.streaming.blockInterval	Interval at which data received by Spark Streaming receivers is chunked into blocks of data before storing them in Spark. Minimum recommended - 50 ms		350	false	false
spark.streaming.kafka.maxRatePerPartition	Maximum rate (number of records per second) at which data will be read from each Kafka partition		5000	false	false

spark.streaming.backpressure.enabled	This enables the Spark Streaming to control the receiving rate based on the current batch scheduling delays and processing times so that the system receives only as fast as the system can process.		false	false	false
spark.streaming.unpersist	Force RDDs generated and persisted by Spark Streaming to be automatically unpersisted from Spark's memory. The raw input data received by Spark Streaming is also automatically cleared. Setting this to false will allow the raw data and persisted RDDs to be accessible outside the streaming application as they will not be cleared automatically. But it comes at the cost of higher memory usage in Spark.		false	false	false
spark.ui.port	No Description Provided.		4050	false	false
spark.streaming.kafka.maxRetries	No Description Provided.		-1	false	false
spark.streaming.receiver.maxRate	Maximum rate (number of records per second) at which data will be read from each Kafka partition		3	false	false

Continued on next page

Table 13 – continued from previous page

Name	Description	Allowable Values	Default Value	Sensitive	El
spark.streaming.ui.retainedBatches	How many batches the Spark Streaming UI and status APIs remember before garbage collecting.		200	false	false
spark.streaming.receiver.writeAheadLog.enable	Enable write ahead logs for receivers. All the input data received through receivers will be saved to write ahead logs that will allow it to be recovered after driver failures.		false	false	false
spark.yarn.maxAppAttempts	Because Spark driver and Application Master share a single JVM, any error in Spark driver stops our long-running job. Fortunately it is possible to configure maximum number of attempts that will be made to re-run the application. It is reasonable to set higher value than default 2 (derived from YARN cluster property yarn.resourcemanager.am.max-attempts). 4 works quite well, higher value may cause unnecessary restarts even if the reason of the failure is permanent.		4	false	false
spark.yarn.am.attemptFailuresValidityInterval	If the application runs for days or weeks without restart or redeployment on highly utilized cluster, 4 attempts could be exhausted in few hours. To avoid this situation, the attempt counter should be reset on every hour of so.		1h	false	false
spark.yarn.max.executor.failures	Maximum number of executor failures before the application fails. By default it is max(2 * num executors, 3), well suited for batch jobs but not for long-running jobs. The property comes with corresponding validity interval which also should be set.8 * num_executors		20	false	false
spark.yarn.executor.failuresValidityInterval	If the application runs for days or weeks without restart or redeployment on highly utilized cluster, x attempts could be exhausted in few hours. To avoid this situation, the attempt counter should be reset on every hour of so.		1h	false	false
spark.task.maxFailures	For long-running jobs you could also consider to boost maximum number of task failures before giving up the job. By default tasks will be retried 4 times and then job fails.		8	false	false
spark.memory.fraction	expresses the size of M as a fraction of the (JVM heap space - 300MB) (default 0.75). The rest of the space (25%) is reserved for user data structures, internal metadata in Spark, and safeguarding against OOM errors in the case of sparse and unusually large records.		0.6	false	false

Continued on next page

Table 13 – continued from previous page

Name	Description	Allowable Values	Default Value	Sensitive	EL
spark.memory.storageFraction	Expressed the size of R as a fraction of M (default 0.5). R is the storage space within M where cached blocks immune to being evicted by execution.		0.5	false	false
spark.scheduler.mode	The scheduling mode between jobs submitted to the same SparkContext. Can be set to FAIR to use fair sharing instead of queueing jobs one after another. Useful for multi-user services.	FAIR (fair sharing), FIFO (queueing jobs one after another)	FAIR	false	false
spark.properties.file.path	file path using –properties-file option while submitting spark job		null	false	false
java.library.path	The java library path to use with mesos.		null	false	false
spark.cores.max	The maximum number of total executor core with mesos.		null	false	false
remote.api.baseUrl	The base URL of the remote server providing logisland configuration		null	false	false
remote.api.polling.rate	Remote api polling rate in milliseconds		null	false	false
remote.api.push.rate	Remote api configuration push rate in milliseconds		null	false	false
remote.api.timeout.connect	Remote api connection timeout in milliseconds		10000	false	false
remote.api.auth.user	The basic authentication user for the remote api endpoint.		null	false	false
remote.api.auth.password	The basic authentication password for the remote api endpoint.		null	false	false
remote.api.timeout.socket	Remote api default read/write socket timeout in milliseconds		10000	false	false

Common-processors

Find below the list.

Other-processors

Find below the list.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.1

Class

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

User-Agent, clickstream, DMP

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 18: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 19: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

"fields": [{ "name": "timestamp", "type": "long" },{ "name": "remoteHost", "type": "string"},{ "name": "record_type", "type": ["null", "string"], "default": null },{ "name": "record_id", "type": ["null", "string"], "default": null },{ "name": "location", "type": ["null", "string"], "default": null },{ "name": "hitType", "type": ["null", "string"], "default": null },{ "name": "eventCategory", "type": ["null", "string"], "default": null },{ "name": "eventAction", "type": ["null", "string"], "default": null },{ "name": "eventLabel", "type": ["null", "string"], "default": null },{ "name": "localPath", "type": ["null", "string"], "default": null },{ "name": "q", "type": ["null", "string"], "default": null },{ "name": "n", "type": ["null", "int"], "default": null },{ "name": "referer", "type": ["null", "string"], "default": null },{ "name": "viewportPixelWidth", "type": ["null", "int"], "default": null },{ "name": "viewportPixelHeight", "type": ["null", "int"], "default": null },{ "name": "screenPixelWidth", "type": ["null", "int"], "default": null },{ "name": "screenPixelHeight", "type": ["null", "int"], "default": null },{ "name": "partyId", "type": ["null", "string"], "default": null },{ "name": "sessionId", "type": ["null", "string"], "default": null },{ "name": "pageViewId", "type": ["null", "string"], "default": null },{ "name": "is_newSession", "type": ["null", "boolean"],"default": null },{ "name": "userAgentString", "type": ["null", "string"], "default": null },{ "name": "pageType", "type": ["null", "string"], "default": null },{ "name": "UserId", "type": ["null", "string"], "default": null },{ "name": "B2Bunit", "type": ["null", "string"], "default": null },{ "name": "pointOfService", "type": ["null", "string"], "default": null },{ "name": "companyID", "type": ["null", "string"], "default": null },{ "name": "GroupCode", "type": ["null", "string"], "default": null },{ "name": "userRoles", "type": ["null", "string"], "default": null },{ "name": "is_PunchOut", "type": ["null", "string"], "default": null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample

- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

Table 22: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 23: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 24: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 25: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 26: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web

session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webAnalytics.IncrementalWebSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 27: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, debug information are logged.		false	false	false
es.session.index.field	Name of the field in the record defining the ES index containing the web session documents.		null	false	false
es.session.type.name	Name of the ES type of web session documents.		null	false	false
es.event.index.prefix	Prefix of the index containing the web event documents.		null	false	false
es.event.type.name	Name of the ES type of web event documents.		null	false	false
es.mapping.event.to.session.index.name	Name of the ES index containing the mapping of web session documents.		null	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false
session.timeout	session timeout in sec		1800	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
newSessionReason.out.field	the name of the field containing the reason why a new session was created => will override default value if set		reasonForNewSession	false	false
transactionIds.out.field	the name of the field containing all transactionIds => will override default value if set		transactionIds	false	false
source_of_traffic.suffix	Prefix for the source of the traffic related fields		source_of_traffic	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false

Extra informations

---

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 28: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 29: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

> **Warning:** don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 30: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 31: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{
"conn": {
"id.resp_p": 9092,
"resp_pkts": 0,
"resp_ip_bytes": 0,
"local_orig": true,
"orig_ip_bytes": 0,
"orig_pkts": 0,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 36: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 38: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 39: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

setSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the setSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

transactionIds.out.field	the name of the field containing all transactionIds => will override default value if set		transactionIds	false	false
source_of_traffic.suffix	Prefix for the source of the traffic related fields		source_of_traffic	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false

Extra informations

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 45: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 46: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 47: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Table 50: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 52: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 53: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 54: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 55: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 57: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 58: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 59: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 60: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Table 64: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 65: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 68: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 70: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 71: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 72: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 75: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 77: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 78: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 79: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 82: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 83: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 84: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 85: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchQuery

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 86: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 87: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 90: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 93: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 95: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 96: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 97: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 99: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 100: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 102: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 103: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 104: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 107: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 108: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 114: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 115: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 116: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 117: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

Class

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 118: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 120: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 121: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 122: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 127: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 128: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 129: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Class

com.hurence.logisland.processor.webAnalytics.ConsolidateSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 130: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

Class

com.hurence.logisland.processor.DetectOutliers

Tags

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 132: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 133: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 134: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 135: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```

policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 137: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

“record_time”: 1487597792782

“record_type”: “conn”

“id_resp_p”: 9092

“resp_pkts”: 0

“resp_ip_bytes”: 0

“local_orig”: true

“orig_ip_bytes”: 0

“orig_pkts”: 0

“missed_bytes”: 0

“history”: “Cc”

“tunnel_parents”: []

“id_orig_p”: 56762

“local_resp”: true

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.bro.ParseBroEvent

Tags

bro, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 138: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

“id.resp_h”: “172.17.0.3”,

"ts": 1487596886.953917
}
}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"
"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 140: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 145: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 146: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Table 147: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 148: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 149: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 150: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 152: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 153: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 154: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 157: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 158: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 159: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 160: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

“record_time”: 1487597792782

“record_type”: “conn”

“id_resp_p”: 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 165: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 168: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webAnalytics.SetSourceOfTraffic

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 170: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 171: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 172: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 174: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 175: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 177: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 178: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 179: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 182: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 183: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 184: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 185: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 189: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 190: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 195: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 196: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 197: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 200: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 202: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 203: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 204: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 207: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 208: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 209: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 210: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 215: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 218: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 220: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 221: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 222: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 224: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 225: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 227: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 228: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 229: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 232: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 233: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 240: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 241: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 242: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

Table 243: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 245: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 246: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 247: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 252: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 253: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 254: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 255: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

(default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

Class

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 257: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 258: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 259: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 260: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 261: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 262: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 263: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 265: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 270: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 271: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 273: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 274: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 275: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 277: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 278: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 279: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 282: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 283: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 284: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 285: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 290: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 295: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 296: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 297: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 299: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Table 300: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 302: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 303: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 304: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 308: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 309: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 310: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"proto": "tcp"
"id_resp_h": "172.17.0.3"
"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 314: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 315: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 320: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 321: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 322: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 325: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.MultiGetElasticsearch

- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 327: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 328: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 329: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webAnalytics.ConsolidateSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 330: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.out.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

Extra informations

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

Class

com.hurence.logisland.processor.DetectOutliers

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 332: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 333: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 334: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 335: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchQuery

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 336: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 337: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 340: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 343: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 345: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 346: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 347: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 349: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 350: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 352: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 353: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 354: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 357: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 358: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 359: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 360: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 365: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 366: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 367: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

Class

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 368: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 370: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 371: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 372: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 377: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 378: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 379: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 380: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 382: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 383: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 384: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 385: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```

error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"history": "Cc"

"tunnel_parents": []

"id_orig_p": 56762

"local_resp": true

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 388: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 390: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 395: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 396: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Table 397: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 399: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 400: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 402: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 403: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 404: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 407: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 408: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 409: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 410: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 415: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 420: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 421: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 422: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 424: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Table 425: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 427: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 428: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 429: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 432: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 433: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 434: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 435: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

“record_time”: 1487597792782

“record_type”: “conn”

“id_resp_p”: 9092

“resp_pkts”: 0

“resp_ip_bytes”: 0

“local_orig”: true

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Table 439: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 440: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 445: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 446: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 447: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 450: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 452: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 453: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 454: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 457: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 458: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 459: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 460: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchQuery

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 461: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 462: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 465: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 468: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 470: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 471: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 472: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 474: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 475: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 477: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 478: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 479: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 482: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 483: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 484: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 485: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

netflow, security

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 489: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 490: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 491: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 492: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

User-Agent, clickstream, DMP

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 493: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 495: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 496: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 497: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 502: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 503: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 504: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

Class

com.hurence.logisland.processor.webAnalytics.ConsolidateSession

Tags

analytics, web, session

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 505: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.out.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.out.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.out.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.out.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.out.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.out.field	The name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.out.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.out.field	The name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

(default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 507: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 508: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 509: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 510: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"history": "Cc"

"tunnel_parents": []

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 513: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 515: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 520: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 521: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Table 522: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 523: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 524: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 525: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 527: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 528: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 529: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 532: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 533: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 534: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 535: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

“id.resp_h”: “172.17.0.3”,

“ts”: 1487596886.953917

}

}

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

“@timestamp”: “2017-02-20T13:36:32Z”

“record_id”: “6361f80a-c5c9-4a16-9045-4bb51736333d”

“record_time”: 1487597792782

“record_type”: “conn”

“id_resp_p”: 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 540: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 543: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

> the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Class

com.hurence.logisland.processor.webAnalytics.SetSourceOfTraffic

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 545: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 546: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 547: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 549: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Table 550: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 552: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 553: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 554: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 558: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 559: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 560: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

“local_resp”: true,

“uid”: “Ct3Ms01I3Yc6pmMZx7”,

“conn_state”: “OTH”,

“id.orig_h”: “172.17.0.2”,

“proto”: “tcp”,

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"proto": "tcp"

"id_resp_h": "172.17.0.3"

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 564: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false
output.record.type	the output type of the record		netflowevent	false	false
enrich.record	Enrich data. If enabledthe netflow record is enriched with inferred data		false	false	false

Extra informations

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 565: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 570: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.3.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 571: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 572: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.3.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

hbase, scan, fetch, get, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 575: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.3.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 577: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.3.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 578: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 579: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.3.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 582: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.3.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 583: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.3.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 584: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 585: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

---

MatchQuery

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.3.0

Class

com.hurence.logisland.processor.MatchQuery

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 586: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 587: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.3.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 590: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 593: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 595: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 596: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 597: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 599: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 600: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 602: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 603: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 604: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”:

“viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field: Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 607: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 608: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"ts": 1487596886.953917

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 615: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

Table 616: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
decode.fields	List of fields (URL) to decode		null	false	false
charset	Charset to use to decode the URL		UTF-8	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 617: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
fields to decode	a default value	Decode one or more fields from the record		null	false

Extra informations

Decode one or more field containing an URL with possibly special chars encoded.

ParseUserAgent

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

Module

com.hurence.logisland:logisland-processor-useragent:1.4.0

com.hurence.logisland.processor.useragent.ParseUserAgent

Tags

User-Agent, clickstream, DMP

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 618: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
cache.enabled	Enable caching. Caching to avoid to redo the same computation for many identical User-Agent strings.		true	false	false
cache.size	Set the size of the cache.		1000	false	false
useragent.field	Must contain the name of the field that contains the User-Agent value in the incoming record.		null	false	false
useragent.keep	Defines if the field that contained the User-Agent must be kept or not in the resulting records.		true	false	false
confidence.enabled	Enable confidence reporting. Each field will report a confidence attribute with a value comprised between 0 and 10000.		false	false	false
ambiguity.enabled	Enable ambiguity reporting. Reports a count of ambiguities.		false	false	false
fields	Defines the fields to be returned.		DeviceClass, DeviceName, DeviceBrand, DeviceCpu, DeviceFirmwareVersion, DeviceVersion, OperatingSystemClass, OperatingSystemName, OperatingSystemVersion, OperatingSystemNameVersion, OperatingSystemVersionBuild, LayoutEngineClass, LayoutEngineName, LayoutEngineVersion, LayoutEngineVersionMajor, LayoutEngineNameVer-	false	false

Extra informations

The user-agent processor allows to decompose User-Agent value from an HTTP header into several attributes of interest. There is no standard format for User-Agent strings, hence it is not easily possible to use regexp to handle them. This processor rely on the YAUAA library to do the heavy work.

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 620: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 621: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	Expression Language
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 622: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

PutHBaseCell

Adds the Contents of a Record to HBase as the value of a single cell

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.PutHBaseCell

Tags

hadoop, hbase

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 627: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 628: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 629: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

Module

com.hurence.logisland:logisland-processor-web-analytics:1.4.0

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 630: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		null	false	false
session.timeout	session timeout in sec		1800	false	false
sessionid.field	the name of the field containing the session id => will override default value if set		sessionId	false	false
timestamp.field	the name of the field containing the timestamp => will override default value if set		h2kTimestamp	false	false
visitedpage.field	the name of the field containing the visited page => will override default value if set		location	false	false
userid.field	the name of the field containing the userId => will override default value if set		userId	false	false
fields.to.return	the list of fields to return		null	false	false
firstVisitedPage.field	the name of the field containing the first visited page => will override default value if set		firstVisitedPage	false	false
lastVisitedPage.field	the name of the field containing the last visited page => will override default value if set		lastVisitedPage	false	false
isSessionActive.field	the name of the field stating whether the session is active or not => will override default value if set		is_sessionActive	false	false
sessionDuration.field	the name of the field containing the session duration => will override default value if set		sessionDuration	false	false
eventsCounter.field	the name of the field containing the session duration => will override default value if set		eventsCounter	false	false
firstEventDateTime.field	the name of the field containing the date of the first event => will override default value if set		firstEventDateTime	false	false
lastEventDateTime.field	the name of the field containing the date of the last event => will override default value if set		lastEventDateTime	false	false
sessionInactivityDuration.field	the name of the field containing the session inactivity duration => will override default value if set		sessionInactivityDuration	false	false

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

Module

com.hurence.logisland:logisland-processor-outlier-detection:1.4.0

Class

com.hurence.logisland.processor.DetectOutliers

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 632: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 633: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 634: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 635: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 636: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 637: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

Query matching based on Luwak

you can use this processor to handle custom events defined by lucene queries a new record is added to output each time a registered query is matched

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"history": "Cc"

"tunnel_parents": []

"id_orig_p": 56762

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 638: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug. If enabled, the original JSON string is embedded in the record_value field of the record.		false	false	false

Extra informations

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

“conn”: {

“id.resp_p”: 9092,

“resp_pkts”: 0,

“resp_ip_bytes”: 0,

“local_orig”: true,

“orig_ip_bytes”: 0,

“orig_pkts”: 0,

“missed_bytes”: 0,

“history”: “Cc”,

“tunnel_parents”: [],

“id.orig_p”: 56762,

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 640: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:

the duration between the web session and the web event must not exceed the specified time-out, the web session and the web event must have timestamps within the same day (at midnight a new web session is created), source of traffic (campaign, ...) must be the same on the web session and the web event.

When a breaking rule is detected, a new web session is created with a new session identifier where as remaining web-events still have the original session identifier. The new session identifier is the original session suffixed with the character '#' followed with an incremented counter. This new session identifier is also set on the remaining web-events. Finally when all web events were applied, all web events -potentially modified with a new session identifier- are save in elasticsearch. And web sessions are passed to the next processor.

WebSession information are: - first and last visited page - first and last timestamp of processed event - total number of processed events - the userId - a boolean denoting if the web-session is still active or not - an integer denoting the duration of the web-sessions - optional fields that may be retrieved from the processed events

---

SetSourceOfTraffic

Compute the source of traffic of a web session. Users arrive at a website or application through a variety of sources, including advertising/paying campaigns, search engines, social networks, referring sites or direct access. When analysing user experience on a webshop, it is crucial to collect, process, and report the campaign and traffic-source data. To compute the source of traffic of a web session, the user has to provide the utm_* related properties if available i-e: **utm_source.field**, **utm_medium.field**, **utm_campaign.field**, **utm_content.field**, **utm_term.field**) , the referer (**referer.field** property) and the first visited page of the session (**first.visited.page.field** property). By default the source of traffic information are placed in a flat structure (specified by the **source_of_traffic.suffix** property with a default value of source_of_traffic). To work properly the SetSourceOfTraffic processor needs to have access to an Elasticsearch index containing a list of the most popular search engines and social networks. The ES index (specified by the **es.index** property) should be structured such that the _id of an ES document MUST be the name of the domain. If the domain is a search engine, the related ES doc MUST have a boolean field (default being search_engine) specified by the property **es.search_engine.field** with a value set to true. If the domain is a social network , the related ES doc MUST have a boolean field (default being social_network) specified by the property **es.social_network.field** with a value set to true.

Table 645: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
referer.field	Name of the field containing the referer value in the session		referer	false	false
first.visited.page.field	Name of the field containing the first visited page in the session		firstVisitedPage	false	false
utm_source.field	Name of the field containing the utm_source value in the session		utm_source	false	false
utm_medium.field	Name of the field containing the utm_medium value in the session		utm_medium	false	false
utm_campaign.field	Name of the field containing the utm_campaign value in the session		utm_campaign	false	false
utm_content.field	Name of the field containing the utm_content value in the session		utm_content	false	false
utm_term.field	Name of the field containing the utm_term value in the session		utm_term	false	false
source_of_traffic.suffix	Suffix for the source of the traffic related fields		source_of_traffic	false	false
source_of_traffic.hierarchical	Should the additional source of trafic information fields be added under a hierarchical father field or not.		false	false	false
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
cache.service	Name of the cache service to use.		null	false	false
cache.validity.timeout	Time out validity (in seconds) of an entry in the cache.		0	false	false
debug	If true, an additional debug field is added. If the source info fields prefix is X, a debug field named X_from_cache contains a boolean value to indicate the origin of the source fields. The default value for this property is false (debug is disabled).		false	false	false
es.index	Name of the ES index containing the list of search engines and social network.		null	false	false
es.type	Name of the ES type to use.		default	false	false
es.search_engine.field	Name of the ES field used to specify that the domain is a search engine.		search_engine	false	false
es.social_network.field	Name of the ES field used to specify that the domain is a social network.		social_network	false	false

Extra informations

IpToFqdn

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

Module

com.hurence.logisland:logisland-processor-enrichment:1.4.0

Class

com.hurence.logisland.processor.enrichment.IpToFqdn

Tags

dns, ip, fqdn, domain, address, fqhn, reverse, resolution, enrich

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 646: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
ip.address.field	The name of the field containing the ip address to use.		null	false	false
fqdn.field	The field that will contain the full qualified domain name corresponding to the ip address.		null	false	false
overwrite.fqdn.field	If the field should be overwritten when it already exists.		false	false	false
cache.service	The name of the cache service to use.		null	false	false
cache.max.time	The amount of time, in seconds, for which a cached FQDN value is valid in the cache service. After this delay, the next new request to translate the same IP into FQDN will trigger a new reverse DNS request and the result will overwrite the entry in the cache. This allows two things: if the IP was not resolved into a FQDN, this will get a chance to obtain a FQDN if the DNS system has been updated, if the IP is resolved into a FQDN, this will allow to be more accurate if the DNS system has been updated. A value of 0 seconds disables this expiration mechanism. The default value is 84600 seconds, which corresponds to new requests triggered every day if a record with the same IP passes every day in the processor.		84600	false	false
resolution.timeout	The amount of time, in milliseconds, to wait at most for the resolution to occur. This avoids to block the stream for too much time. Default value is 1000ms. If the delay expires and no resolution could occur before, the FQDN field is not created. A special value of 0 disables the logisland timeout and the resolution request may last for many seconds if the IP cannot be translated into a FQDN by the underlying operating system. In any case, whether the timeout occurs in logisland of in the operating system, the fact that a timeout occurs is kept in the cache system so that a resolution request for the same IP will not occur before the cache entry expires.		1000	false	false
debug	If true, some additional debug fields are added. If the FQDN field is named X, a debug field named X_os_resolution_time_ms contains the resolution time in ms (using the operating system, not the cache). This field is added whether the resolution occurs or time is out. A debug field named X_os_resolution_timeout contains a boolean value to indicate if the timeout occurred. Finally, a debug field named X_from_cache contains a boolean value to indicate the origin of the FQDN field. The default value for this property is false (debug is disabled.		false	false	false

Extra informations

Translates an IP address into a FQDN (Fully Qualified Domain Name). An input field from the record has the IP as value. An new field is created and its value is the FQDN matching the IP address. The resolution mechanism is based on the underlying operating system. The resolution request may take some time, specially if the IP address cannot be translated into a FQDN. For these reasons this processor relies on the logisland cache service so that once a resolution occurs or not, the result is put into the cache. That way, the real request for the same IP is not re-triggered during a certain period of time, until the cache entry expires. This timeout is configurable but by default a request for the same IP is not triggered before 24 hours to let the time to the underlying DNS system to be potentially updated.

IpToGeo

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

Table 647: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
ip.address.field	The name of the field containing the ip address to use.		null	false	false
iptogeo.service	The reference to the IP to Geo service to use.		null	false	false
geo.fields	Comma separated list of geo information fields to add to the record. Defaults to '*', which means to include all available fields. If a list of fields is specified and the data is not available, the geo field is not created. The geo fields are dependant on the underlying defined Ip to Geo service. The currently only supported type of Ip to Geo service is the Maxmind Ip to Geo service. This means that the currently supported list of geo fields is the following:**continent**: the identified continent for this IP address. **continent_code**: the identified continent code for this IP address. **city**: the identified city for this IP address. **latitude**: the identified latitude for this IP address. **longitude**: the identified longitude for this IP address. **location**: the identified location for this IP address, defined as Geo-point expressed as a string with the format: 'latitude,longitude'. **accuracy_radius**: the approximate accuracy radius, in kilometers, around the latitude and longitude for the location. **time_zone**: the identified time zone for this IP address. **subdivision_N**: the identified subdivision for this IP address. N is a one-up number at the end of the attribute name, starting with 0. **subdivision_isocode_N**: the iso code matching the identified subdivision_N. **country**: the identified country for this IP address. **country_isocode**: the iso code for the identified country for this IP address. **postalcode**: the identified postal code for this IP address. **lookup_micros**: the number of microseconds that the geo lookup took. The Ip to Geo service must have the lookup_micros property enabled in order to have this field available.		•	false	false
geo.hierarchical	Should the additional geo information fields be added under a hierarchical father field or not.		true	false	false
geo.hierarchical.suffix	Suffix to use for the field holding geo information. If geo.hierarchical is true, then use this suffix appended to the IP field name to define the father field name. This may be used for instance to distinguish between geo fields with various locales using many Ip to Geo service instances.		_geo	false	false
geo.flat.suffix	Suffix to use for geo information fields when they are flat. If geo.hierarchical is false, then use this suffix appended to the IP field name but before the geo field name. This may be		_geo_	false	false

Extra informations

Looks up geolocation information for an IP address. The attribute that contains the IP address to lookup must be provided in the **ip.address.field** property. By default, the geo information are put in a hierarchical structure. That is, if the name of the IP field is 'X', then the the geo attributes added by enrichment are added under a father field named X_geo. "_geo" is the default hierarchical suffix that may be changed with the **geo.hierarchical.suffix** property. If one wants to put the geo fields at the same level as the IP field, then the **geo.hierarchical** property should be set to false and then the geo attributes are created at the same level as him with the naming pattern X_geo_<geo_field>. "_geo_" is the default flat suffix but this may be changed with the **geo.flat.suffix** property. The IpToGeo processor requires a reference to an Ip to Geo service. This must be defined in the **iptogeo.service** property. The added geo fields are dependant on the underlying Ip to Geo service. The **geo.fields** property must contain the list of geo fields that should be created if data is available for the IP to resolve. This property defaults to "*" which means to add every available fields. If one only wants a subset of the fields, one must define a comma separated list of fields as a value for the **geo.fields** property. The list of the available geo fields is in the description of the **geo.fields** property.

ParseNetworkPacket

The ParseNetworkPacket processor is the LogIsland entry point to parse network packets captured either off-the-wire (stream mode) or in pcap format (batch mode). In batch mode, the processor decodes the bytes of the incoming pcap record, where a Global header followed by a sequence of [packet header, packet data] pairs are stored. Then, each incoming pcap event is parsed into n packet records. The fields of packet headers are then extracted and made available in dedicated record fields. See the Capturing Network packets tutorial for an example of usage of this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.networkpacket.ParseNetworkPacket

Tags

PCap, security, IDS, NIDS

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 648: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
debug	Enable debug.		false	false	false
flow.mode	Flow Mode. Indicate whether packets are provided in batch mode (via pcap files) or in stream mode (without headers). Allowed values are batch and stream.	batch, stream	null	false	false

Extra informations

No additional information is provided

BulkAddElasticsearch

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.BulkAddElasticsearch

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 649: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
default.index	The name of the index to insert into		null	false	**true**
default.type	The type of this document (used by Elasticsearch for indexing and searching)		null	false	**true**
timebased.index	do we add a date suffix	no (no date added to default index), today (today's date added to default index), yesterday (yesterday's date added to default index)	no	false	false
es.index.field	the name of the event field containing es index name => will override index value if set		null	false	false
es.type.field	the name of the event field containing es doc type => will override type value if set		null	false	false

Extra informations

Indexes the content of a Record in Elasticsearch using elasticsearch's bulk processor.

FetchHBaseRow

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

Module

com.hurence.logisland:logisland-processor-hbase:1.4.0

Class

com.hurence.logisland.processor.hbase.FetchHBaseRow

Tags

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 650: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to fetch from.		null	false	**true**
row.identifier.field	The field containing the identifier of the row to fetch.		null	false	**true**
columns.field	The field containing an optional comma-separated list of “”<colFamily>:<colQualifier>”” pairs to fetch. To return all columns for a given family, leave off the qualifier such as “”<colFamily1>,<colFamily2>””.		null	false	**true**
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
table.name.default	The table to use if table name field is not set		null	false	false

Extra informations

Fetches a row from an HBase table. The Destination property controls whether the cells are added as flow file attributes, or the row is written to the flow file content as JSON. This processor may be used to fetch a fixed row on a interval by specifying the table and row id directly in the processor, or it may be used to dynamically fetch rows by referencing the table and row id from incoming flow files.

MultiGetElasticsearch

Retrieves a content indexed in elasticsearch using elasticsearch multiget queries. Each incoming record contains information regarding the elasticsearch multiget query that will be performed. This information is stored in record fields whose names are configured in the plugin properties (see below) :

- index (String) : name of the elasticsearch index on which the multiget query will be performed. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.

- type (String) : name of the elasticsearch type on which the multiget query will be performed. This field is not mandatory.
- ids (String) : comma separated list of document ids to fetch. This field is mandatory and should not be empty, otherwise an error output record is sent for this specific incoming record.
- includes (String) : comma separated list of patterns to filter in (include) fields to retrieve. Supports wildcards. This field is not mandatory.
- excludes (String) : comma separated list of patterns to filter out (exclude) fields to retrieve. Supports wildcards. This field is not mandatory.

Each outcoming record holds data of one elasticsearch retrieved document. This data is stored in these fields :

- index (same field name as the incoming record) : name of the elasticsearch index.
- type (same field name as the incoming record) : name of the elasticsearch type.
- id (same field name as the incoming record) : retrieved document id.
- a list of String fields containing :
  - field name : the retrieved field name
  - field value : the retrieved field value

Module

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 652: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
hbase.client.service	The instance of the Controller Service to use for accessing HBase.		null	false	false
table.name.field	The field containing the name of the HBase Table to put data into		null	false	**true**
row.identifier.field	Specifies field containing the Row ID to use when inserting data into HBase		null	false	**true**
row.identifier.encoding.strategy	Specifies the data type of Row ID used when inserting data into HBase. The default behavior is to convert the row id to a UTF-8 byte array. Choosing Binary will convert a binary formatted string to the correct byte[] representation. The Binary option should be used if you are using Binary row keys in HBase	String (Stores the value of row id as a UTF-8 String.), Binary (Stores the value of the rows id as a binary byte array. It expects that the row id is a binary formatted string.)	String	false	false
column.family.field	The field containing the Column Family to use when inserting data into HBase		null	false	**true**
column.qualifier.field	The field containing the Column Qualifier to use when inserting data into HBase		null	false	**true**
batch.size	The maximum number of Records to process in a single execution. The Records will be grouped by table, and a single Put per table will be performed.		25	false	false
record.schema	the avro schema definition for the Avro serialization		null	false	false
record.serializer	the serializer needed to i/o the record in the HBase row	com.hurence.logisland.serializer.KryoSerializer (serialize events as json blocs), com.hurence.logisland.serializer.JsonSerializer (serialize events as json blocs), com.hurence.logisland.serializer.AvroSerializer (serialize events as avro blocs), none (send events as bytes)	com.hurence.logisland.serializer.KryoSerializer	false	false
table.name.default	The table table to use if table name field is not set		null	false	false
column.family.default	The column family to use if column family field is not set		null	false	false
column.qualifier.default	The column qualifier to use if column qualifier field is not set		null	false	false

Extra informations

Adds the Contents of a Record to HBase as the value of a single cell.

EvaluateXPath

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

Module

com.hurence.logisland:logisland-processor-xml:1.4.0

Class

com.hurence.logisland.processor.xml.EvaluateXPath

Tags

XML, evaluate, XPath

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 653: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
source	Indicates the attribute containing the xml data to evaluate xpath against.		null	false	false
validate_dtd	Specifies whether or not the XML content should be validated against the DTD.	true, false	true	false	false
conflict.resolution.policy	What to do when a field with the same name already exists ?	overwrite_existing (if field already exist), keep_only_old_field (keep only old field)	keep_only_old_field	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 654: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
An attribute	An XPath expression	the attribute is set to the result of the XPath Expression.		null	false

Extra informations

Evaluates one or more XPaths against the content of a record. The results of those XPaths are assigned to new attributes in the records, depending on configuration of the Processor. XPaths are entered by adding user-defined properties; the name of the property maps to the Attribute Name into which the result will be placed. The value of the property must be a valid XPath expression. If the expression matches nothing, no attributes is added.

ConsolidateSession

The ConsolidateSession processor is the Logisland entry point to get and process events from the Web Analytics.As an example here is an incoming event from the Web Analytics:

“fields”: [{ “name”: “timestamp”, “type”: “long” },{ “name”: “remoteHost”, “type”: “string”},{ “name”: “record_type”, “type”: [“null”, “string”], “default”: null },{ “name”: “record_id”, “type”: [“null”, “string”], “default”: null },{ “name”: “location”, “type”: [“null”, “string”], “default”: null },{ “name”: “hitType”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventCategory”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventAction”, “type”: [“null”, “string”], “default”: null },{ “name”: “eventLabel”, “type”: [“null”, “string”], “default”: null },{ “name”: “localPath”, “type”: [“null”, “string”], “default”: null },{ “name”: “q”, “type”: [“null”, “string”], “default”: null },{ “name”: “n”, “type”: [“null”, “int”], “default”: null },{ “name”: “referer”, “type”: [“null”, “string”], “default”: null },{ “name”: “viewportPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “viewportPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelWidth”, “type”: [“null”, “int”], “default”: null },{ “name”: “screenPixelHeight”, “type”: [“null”, “int”], “default”: null },{ “name”: “partyId”, “type”: [“null”, “string”], “default”: null },{ “name”: “sessionId”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageViewId”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_newSession”, “type”: [“null”, “boolean”],”default”: null },{ “name”: “userAgentString”, “type”: [“null”, “string”], “default”: null },{ “name”: “pageType”, “type”: [“null”, “string”], “default”: null },{ “name”: “UserId”, “type”: [“null”, “string”], “default”: null },{ “name”: “B2Bunit”, “type”: [“null”, “string”], “default”: null },{ “name”: “pointOfService”, “type”: [“null”, “string”], “default”: null },{ “name”: “companyID”, “type”: [“null”, “string”], “default”: null },{ “name”: “GroupCode”, “type”: [“null”, “string”], “default”: null },{ “name”: “userRoles”, “type”: [“null”, “string”], “default”: null },{ “name”: “is_PunchOut”, “type”: [“null”, “string”], “default”: null }]The ConsolidateSession processor groups the records by sessions and compute the duration between now and the last received event. If the distance from the last event is beyond a given threshold (by default 30mn), then the session is considered closed.The ConsolidateSession is building an aggregated session object for each active session.This aggregated object includes: - The actual session duration. - A boolean representing wether the session is considered active or closed. Note: it is possible to ressurect a session if for instance an event arrives after a session has been marked closed. - User related infos: userId, B2Bunit code, groupCode, userRoles, companyId - First visited page: URL - Last visited page: URL The properties to configure the processor are: - sessionid.field: Property name containing the session identifier (default: sessionId). - timestamp.field: Property name containing the timestamp of the event (default: timestamp). - session.timeout: Timeframe of inactivity (in seconds) after which a session is considered closed (default: 30mn). - visitedpage.field:

Property name containing the page visited by the customer (default: location). - fields.to.return: List of fields to return in the aggregated object. (default: N/A)

DetectOutliers

Outlier Analysis: A Hybrid Approach

In order to function at scale, a two-phase approach is taken

For every data point

- Detect outlier candidates using a robust estimator of variability (e.g. median absolute deviation) that uses distributional sketching (e.g. Q-trees)
- Gather a biased sample (biased by recency)
- Extremely deterministic in space and cheap in computation

For every outlier candidate

- Use traditional, more computationally complex approaches to outlier analysis (e.g. Robust PCA) on the biased sample
- Expensive computationally, but run infrequently

This becomes a data filter which can be attached to a timeseries data stream within a distributed computational framework (i.e. Storm, Spark, Flink, NiFi) to detect outliers.

EnrichRecordsElasticsearch

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

Module

com.hurence.logisland:logisland-processor-elasticsearch:1.4.0

Class

com.hurence.logisland.processor.elasticsearch.EnrichRecordsElasticsearch

Tags

elasticsearch

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values, and whether a property supports the Expression Language .

Table 657: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
elasticsearch.client.service	The instance of the Controller Service to use for accessing Elasticsearch.		null	false	false
record.key	The name of field in the input record containing the document id to use in ES multiget query		null	false	**true**
es.index	The name of the ES index to use in multiget query.		null	false	**true**
es.type	The name of the ES type to use in multiget query.		default	false	**true**
es.includes.field	The name of the ES fields to include in the record.		•	false	**true**
es.excludes.field	The name of the ES fields to exclude.		N/A	false	false

Extra informations

Enrich input records with content indexed in elasticsearch using multiget queries. Each incoming record must be possibly enriched with information stored in elasticsearch. Each outcoming record holds at least the input record plus potentially one or more fields coming from of one elasticsearch document.

ExcelExtract

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

Module

com.hurence.logisland:logisland-processor-excel:1.4.0

Class

com.hurence.logisland.processor.excel.ExcelExtract

Tags

excel, processor, poi

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 658: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	El
sheets	Comma separated list of Excel document sheet names that should be extracted from the excel document. If this property is left blank then all of the sheets will be extracted from the Excel document. You can specify regular expressions. Any sheets not specified in this value will be ignored.			false	false
skip.columns	Comma delimited list of column numbers to skip. Use the columns number and not the letter designation. Use this to skip over columns anywhere in your worksheet that you don't want extracted as part of the record.			false	false
field.names	The comma separated list representing the names of columns of extracted cells. Order matters! You should use either field.names either field.row.header but not both together.		null	false	false
skip.rows	The row number of the first row to start processing.Use this to skip over rows of data at the top of your worksheet that are not part of the dataset.Empty rows of data anywhere in the spreadsheet will always be skipped, no matter what this value is set to.		0	false	false
record.type	Default type of record		excel_record	false	false
field.row.header	If set, field names mapping will be extracted from the specified row number. You should use either field.names either field.row.header but not both together.		null	false	false

Extra informations

Consumes a Microsoft Excel document and converts each worksheet's line to a structured record. The processor is assuming to receive raw excel file as input record.

MatchIP

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

```
message:'bad exception'
error_count:[10 TO *]
```

(continues on next page)

(continued from previous page)

```
bytes_out:5000
user_name:tom*
```

Please read the Lucene syntax guide for supported operations

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries

Module

com.hurence.logisland:logisland-processor-querymatcher:1.4.0

Class

com.hurence.logisland.processor.MatchIP

Tags

analytic, percolator, record, record, query, lucene

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 659: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
numeric.fields	a comma separated string of numeric field to be matched		null	false	false
output.record.type	the output type of the record		alert_match	false	false
record.type.update.policy	Record type update policy		overwrite	false	false
policy.onmatch	the policy applied to match events: 'first' (default value) match events are tagged with the name and value of the first query that matched;'all' match events are tagged with all names and values of the queries that matched.		first	false	false
policy.onmiss	the policy applied to miss events: 'discard' (default value) drop events that did not match any query;'forward' include also events that did not match any query.		discard	false	false

Dynamic Properties

Dynamic Properties allow the user to specify both the name and value of a property.

Table 660: dynamic-properties

Name	Value	Description	Allowable Values	Default Value	EL
query	some Lucene query	generate a new record when this query is matched		null	**true**

Extra informations

IP address Query matching (using **'Luwak <http://www.confluent.io/blog/real-time-full-text-search-with-luwak-and-samza/>)'_**

You can use this processor to handle custom events matching IP address (CIDR) The record sent from a matching an IP address record is tagged appropriately.

A query is expressed as a lucene query against a field like for example:

Warning: don't forget to set numeric fields property to handle correctly numeric ranges queries.

ParseBroEvent

The ParseBroEvent processor is the Logisland entry point to get and process Bro events. The Bro-Kafka plugin should be used and configured in order to have Bro events sent to Kafka. See the Bro/Logisland tutorial for an example of usage for this processor. The ParseBroEvent processor does some minor pre-processing on incoming Bro events from the Bro-Kafka plugin to adapt them to Logisland.

Basically the events coming from the Bro-Kafka plugin are JSON documents with a first level field indicating the type of the event. The ParseBroEvent processor takes the incoming JSON document, sets the event type in a record_type field and sets the original sub-fields of the JSON event as first level fields in the record. Also any dot in a field name is transformed into an underscore. Thus, for instance, the field id.orig_h becomes id_orig_h. The next processors in the stream can then process the Bro events generated by this ParseBroEvent processor.

As an example here is an incoming event from Bro:

{

"conn": {

"id.resp_p": 9092,

"resp_pkts": 0,

"resp_ip_bytes": 0,

"local_orig": true,

"orig_ip_bytes": 0,

"orig_pkts": 0,

"missed_bytes": 0,

"history": "Cc",

"tunnel_parents": [],

"id.orig_p": 56762,

"local_resp": true,

"uid": "Ct3Ms01I3Yc6pmMZx7",

"conn_state": "OTH",

"id.orig_h": "172.17.0.2",

"proto": "tcp",

```
            "id.resp_h": "172.17.0.3",
            "ts": 1487596886.953917
        }
    }
```

It gets processed and transformed into the following Logisland record by the ParseBroEvent processor:

"@timestamp": "2017-02-20T13:36:32Z"

"record_id": "6361f80a-c5c9-4a16-9045-4bb51736333d"

"record_time": 1487597792782

"record_type": "conn"

"id_resp_p": 9092

"resp_pkts": 0

"resp_ip_bytes": 0

"local_orig": true

"orig_ip_bytes": 0

"orig_pkts": 0

"missed_bytes": 0

"history": "Cc"

"tunnel_parents": []

"id_orig_p": 56762

"local_resp": true

"uid": "Ct3Ms01I3Yc6pmMZx7"

"conn_state": "OTH"

ParseNetflowEvent

The Netflow V5 processor is the Logisland entry point to process Netflow (V5) events. NetFlow is a feature introduced on Cisco routers that provides the ability to collect IP network traffic.We can distinguish 2 components:

- Flow exporter: aggregates packets into flows and exports flow records (binary format) towards one or more flow collectors
- Flow collector: responsible for reception, storage and pre-processing of flow data received from a flow exporter

The collected data are then available for analysis purpose (intrusion detection, traffic analysis...) Netflow are sent to kafka in order to be processed by logisland. In the tutorial we will simulate Netflow traffic using nfgen. this traffic will be sent to port 2055. The we rely on nifi to listen of that port for incoming netflow (V5) traffic and send them to a kafka topic. The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

Module

com.hurence.logisland:logisland-processor-cyber-security:1.4.0

Class

com.hurence.logisland.processor.netflow.ParseNetflowEvent

Tags

The Netflow processor could thus treat these events and generate corresponding logisland records. The following processors in the stream can then process the Netflow records generated by this processor.

RunPython

!!!! WARNING !!!!

The RunPython processor is currently an experimental feature : it is delivered as is, with the current set of features and is subject to modifications in API or anything else in further logisland releases without warnings. There is no tutorial yet. If you want to play with this processor, use the python-processing.yml example and send the apache logs of the index apache logs tutorial. The debug stream processor at the end of the stream should output events in stderr file of the executors from the spark console.

This processor allows to implement and run a processor written in python. This can be done in 2 ways. Either directly defining the process method code in the **script.code.process** configuration property or poiting to an external python module script file in the **script.path** configuration property. Directly defining methods is called the inline mode whereas using a script file is called the file mode. Both ways are mutually exclusive. Whether using the inline of file mode, your python code may depend on some python dependencies. If the set of python dependencies already delivered with the Logisland framework is not sufficient, you can use the **dependencies.path** configuration property to give their location. Currently only the nltk python library is delivered with Logisland.

Module

com.hurence.logisland:logisland-processor-scripting:1.4.0

Class

com.hurence.logisland.processor.scripting.python.RunPython

Tags

scripting, python

Properties

In the list below, the names of required properties appear in **bold**. Any other properties (not in bold) are considered optional. The table also indicates any default values.

Table 665: allowable-values

Name	Description	Allowable Values	Default Value	Sensitive	EL
script.code.imports	For inline mode only. This is the python code that should hold the import statements if required.		null	false	false
script.code.init	The python code to be called when the processor is initialized. This is the python equivalent of the init method code for a java processor. This is not mandatory but can only be used if **script.code.process** is defined (inline mode).		null	false	false
script.code.process	The python code to be called to process the records. This is the pyhton equivalent of the process method code for a java processor. For inline mode, this is the only minimum required configuration property. Using this property, you may also optionally define the **script.code.init** and **script.code.imports** properties.		null	false	false
script.path	The path to the user's python processor script. Use this property for file mode. Your python code must be in a python file with the following constraints: let's say your pyhton script is named MyProcessor.py. Then MyProcessor.py is a module file that must contain a class named MyProcessor which must inherits from the Logisland delivered class named AbstractProcessor. You can then define your code in the process method and in the other traditional methods (init...) as you would do in java in a class inheriting from the AbstractProcessor java class.		null	false	false
dependencies.path	The path to the additional dependencies for the user's python code, whether using inline or file mode. This is optional as your code may not have additional dependencies. If you defined **script.path** (so using file mode) and if **dependencies.path** is not defined, Logisland will scan a potential directory named **dependencies** in the same directory where the script file resides and if it exists, any python code located there will be loaded as dependency as needed.		null	false	false
logisland.dependencies.path	The path to the directory containing the python dependencies shipped with logisland. You should not have to tune this parameter.		null	false	false

IncrementalWebSession

This processor creates and updates web-sessions based on incoming web-events. Note that both web-sessions and web-events ar

Firstly, web-events are grouped by their session identifier and processed in chronological order. Then each web-session associated to each group is retrieved from elasticsearch. In case none exists yet then a new web session is created based on the first web event. The following fields of the newly created web session are set based on the associated web event: session identifier, first timestamp, first visited page. Secondly, once created, or retrieved, the web session is updated by the remaining web-events. Updates have impacts on fields of the web session such as event counter, last visited page, session duration, ... Before updates are actually applied, checks are performed to detect rules that would trigger the creation of a new session:
